

Microbial Ecology of Activated Sludge

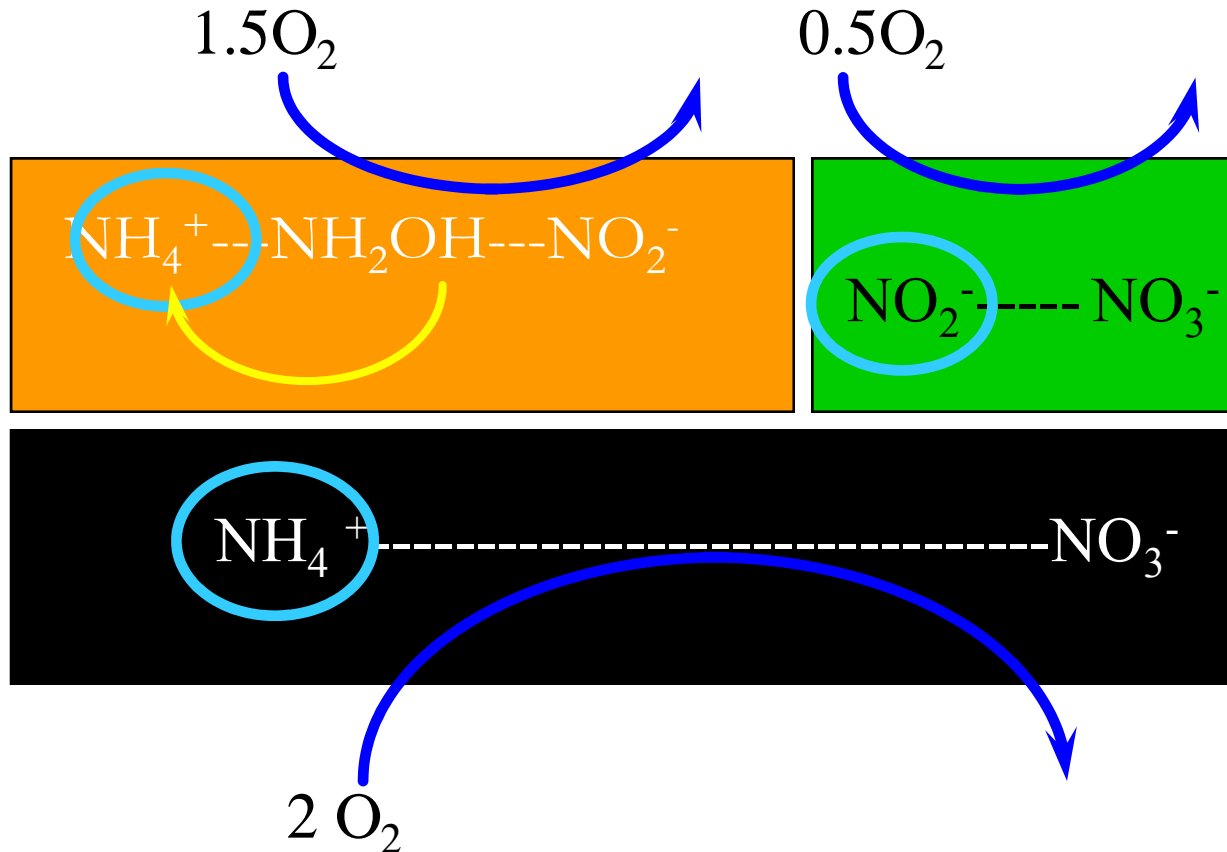

Kartik Chandran
Columbia University

NJWEA AAEES Workshop
100 Years of Activated Sludge
May 12th, 2015

Nitrification is one of the key biological reactions in the N-cycle

Nitrification is a principal step in biological nitrogen removal – increasingly mandated worldwide

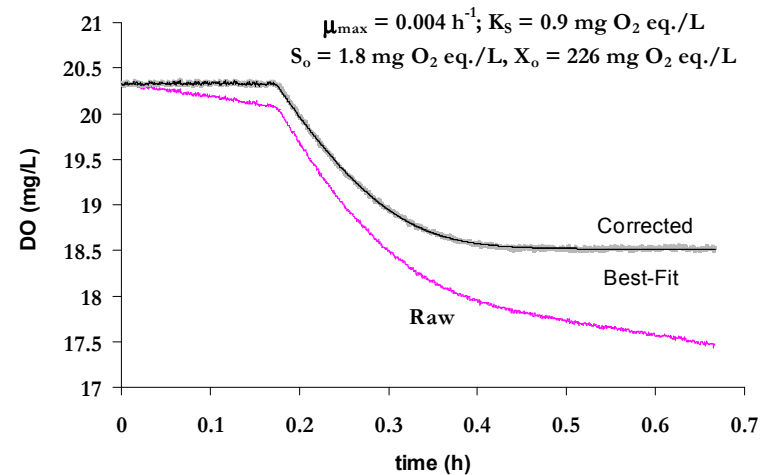

Extant respirometry (oxygen uptake) for biokinetic estimation of nitrification

Extant respirometry schematic

Raw and corrected extant respirograms

$$\mu_X = \frac{\mu_{\max} * X}{1 + K_s / S}$$

plus Y and b for each nitrification step via **real-time assay optimization**

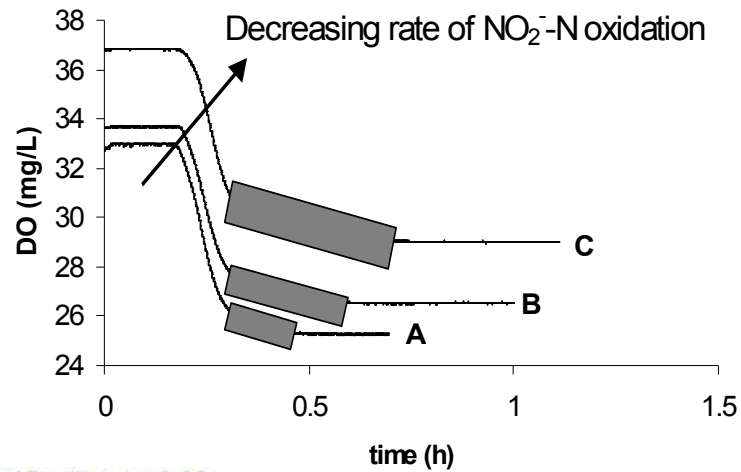

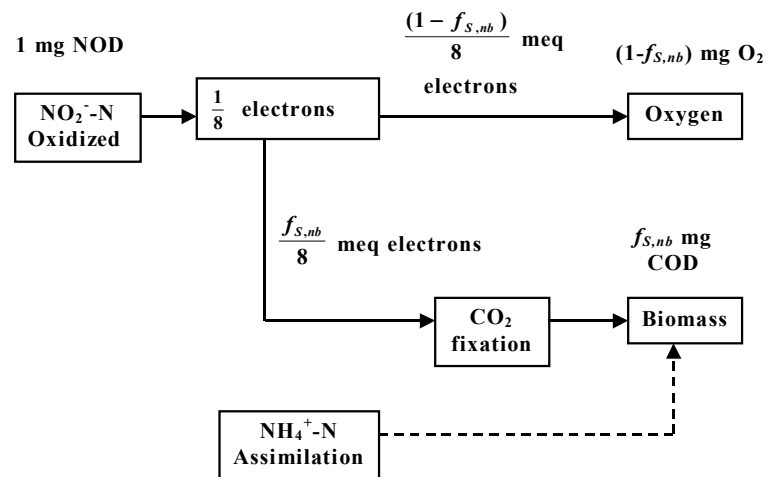

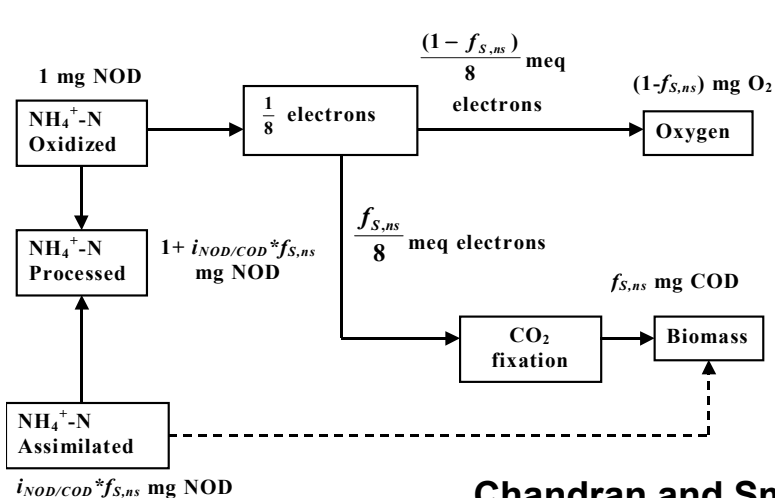

Table I. Elements of the two-step nitrification model.^a

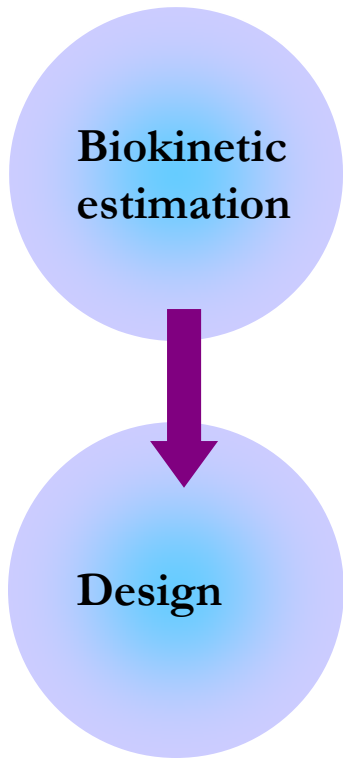

Oxidation by ↓	S_{nh}	S_{no2}	Ou_{ns}	Ou_{nb}	X_{ns}	X_{nb}	Rate expression
X_{ns}	$-\frac{(1 + (0.3 \cdot f_{s,ns}))}{f_{s,ns}}$	$+\frac{1}{3 \cdot f_{s,ns}}$	$+\frac{(1-f_{s,ns})}{f_{s,ns}}$		+1		$\mu_{max,ns} \cdot \frac{X_{ns} \cdot S_{nh}}{K_{S,ns} + S_{nh}}$
X_{nb}		$-\frac{1}{f_{s,nb}}$		$+\frac{(1-f_{s,nb})}{f_{s,nb}}$		+1	$\mu_{max,nb} \cdot \frac{X_{nb} \cdot S_{no2}}{K_{S,nb} + S_{no2}}$

Chandran and Smets, 2000a, 2000b

What is still missing ?

$$\mu_{\max} = \frac{f_S}{(1 - f_S)} * \frac{OUR_{\max}}{X}$$

$$S_{nh,eff} = \frac{K_S \left(\left(\frac{1}{\theta_C} \right) + b_a \right)}{\mu_{\max} - \left(\left(\frac{1}{\theta_C} \right) + b_a \right)}$$

- Accurate descriptors of specific activity are only as good as estimates of target biomass concentration
 - Who is there and how many are there?
 - Challenging in mixed culture environment
 - Traditional lumped descriptors like TSS, VSS are inadequate

Implications of understanding microbial ecology

How do process control responses differ?

Impaired reactor performance is translated into a reduction in “specific” activity

Impaired reactor performance is translated into a reduction in “active” NH_4^+ -N oxidizing biomass fraction

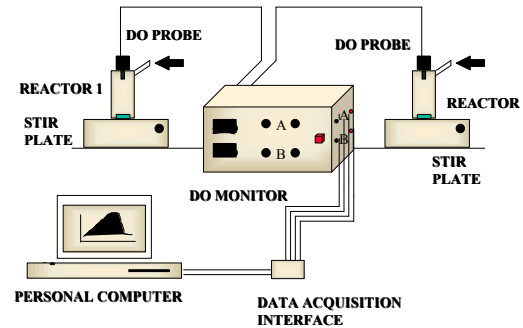

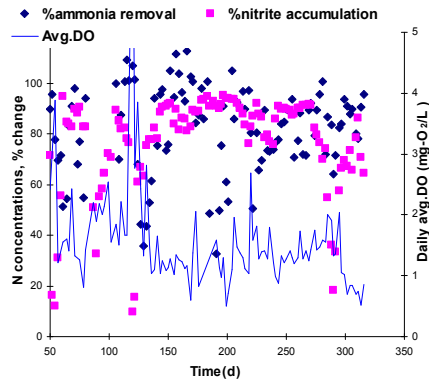

Reduction in μ_{\max}

Reduction in X

Direct microbial abundance enabled estimation of biokinetics

- $Y_{ns} = 0.24 \text{ mg X COD/ N oxidized}$ (Grady et al., 1999)
- $Y_{nb} = 0.1 \text{ mg X COD/N oxidized}$ (Chandran and Smets, 2000)
- mass of a bacterial cell: $2.8 \cdot 10^{-13} \text{ g/cell}$ (Brock Biology of Microorganisms, 2005, 11th ed., Pearson)
- Cellular DNA content: $8.8 \cdot 10^{-16} \text{ g DNA/cell}$ (Kindaichi et al., 2006)
- one copy of 16S rRNA operon copy number per genome (Chain et al., 2003, Starkenburg et al., 2006)

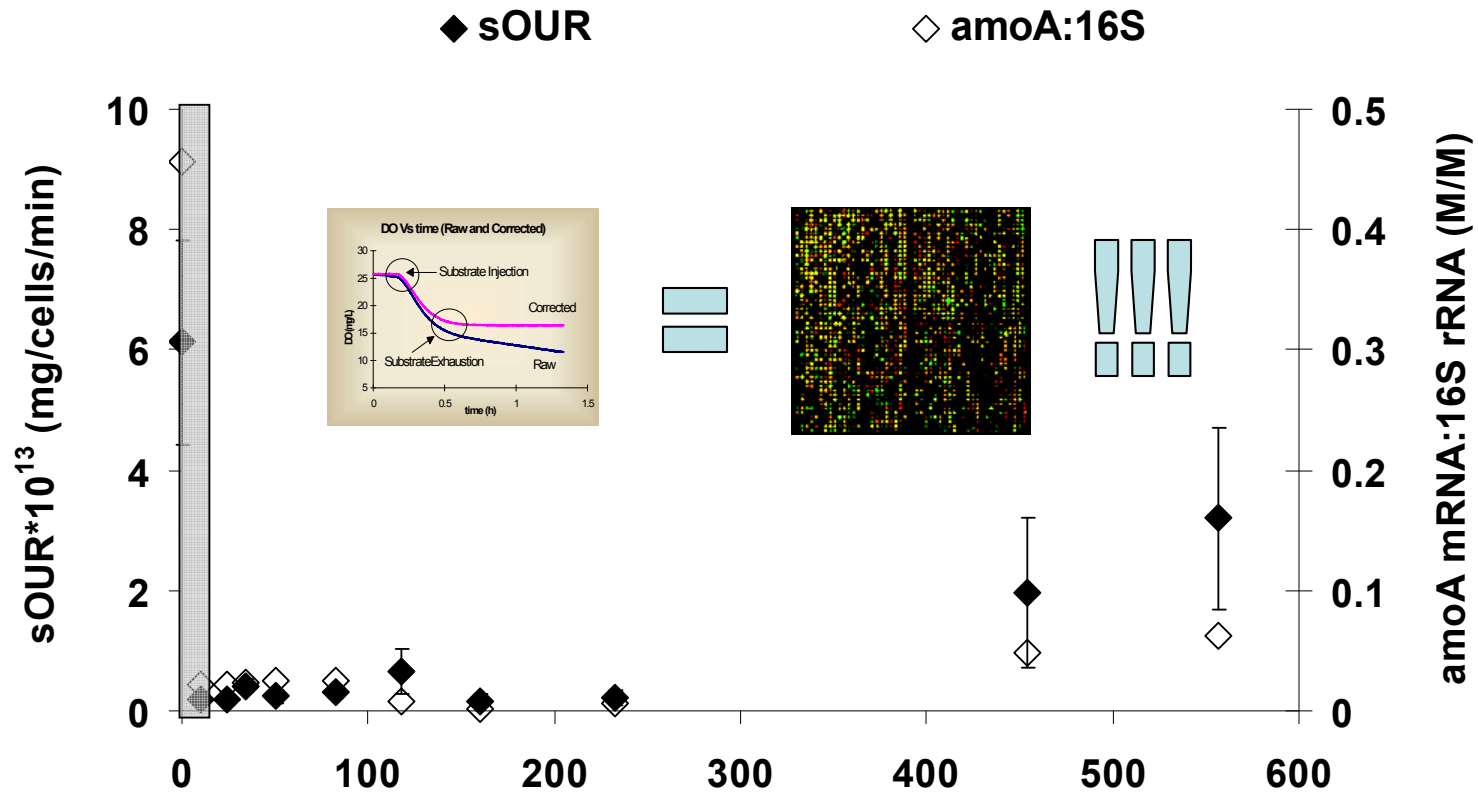

Parameter estimates

Parameter	AOB	NOB	Equation
μ_{\max} (1/d)	2.83 ± 2.46	7.04 ± 5.18	$\mu_{\max} = \frac{Y_{\text{true}}}{(1 - Y_{\text{true}})} * \frac{\left(\frac{dO_2}{dt}\right)_{\max}}{X_{\text{AOB,NOBnb}}}$
Y_{net} (mg X COD/mg N oxidized)	0.15 ± 0.07	0.014 ± 0.007	$Y_{\text{net}} = \frac{X * \tau}{\theta_c * \Delta S}$
b (1/d)	0.37 ± 0.27	2.24 ± 1.25	$b = \frac{\frac{Y_{\text{true}}}{Y_{\text{net}}} - 1}{\theta_c}$

Impact on *amoA* expression

Nitrification specific activity measures strongly parallel gene expression measures

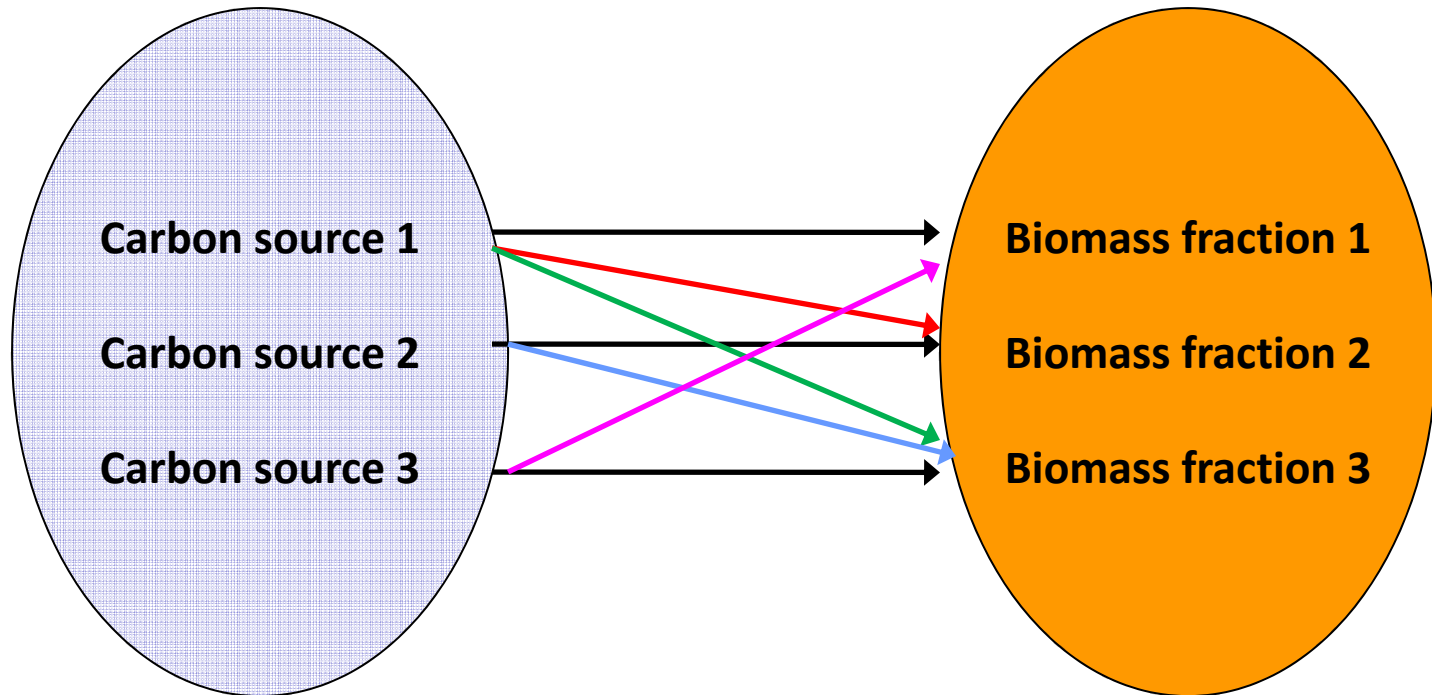

Organic electron donor in engineered denitrification

- Wastewater streams are often limited in readily biodegradable COD to remove N down to very low levels
- Therefore external carbon sources are widely used to enhance N removal
 - Different carbon sources have different rates and active fraction for denitrification
- Selection of the carbon source is thus, key for achieving target N goals
 - WERF Nutrient Challenge Project (Baytshtok et al., 2008, 2009)

Who consumes which organic carbon source in engineered denitrification?

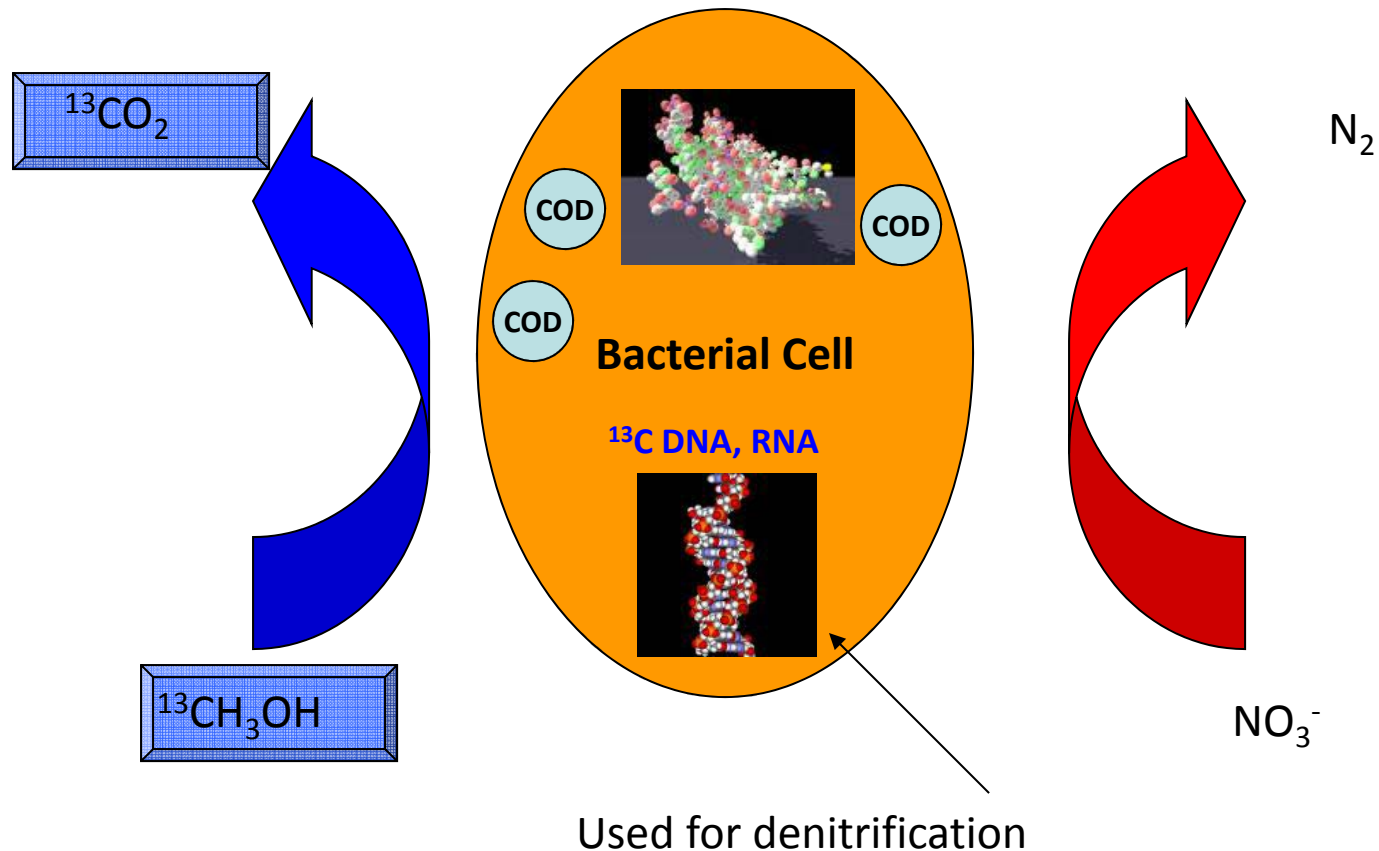

- Do same bacteria utilize all organic C- sources?
- What happens to community structure upon changing organic C-source?
- Implications for process modeling, design and optimization?

Organic carbon uptake during denitrification

Organic carbon uptake during denitrification

Tracking dominant methylotrophic populations in the SBR

- *Methyloversatilis* spp. more abundant than *Hyphomicrobium* spp.
- 'Relatively' stable during methanol feed phase

Tracking dominant methylotrophic populations in the SBR

Phase I

Phase II

Phase III

Survival of methylotrophic populations depended upon their nutritional modes

Slide 16

Chandran5 Need to show N-removal profiles?

Is it the community or activity lagging?

Mention that functional genomics is ongoing

Prof. Kartik Chandran, 7/5/2010

C1 and C2: metabolic pathways

C1 (methanol)

Primary oxidation

C1 transfer

C1 assimilation

C2 (ethanol)

Primary oxidation

Central assimilation

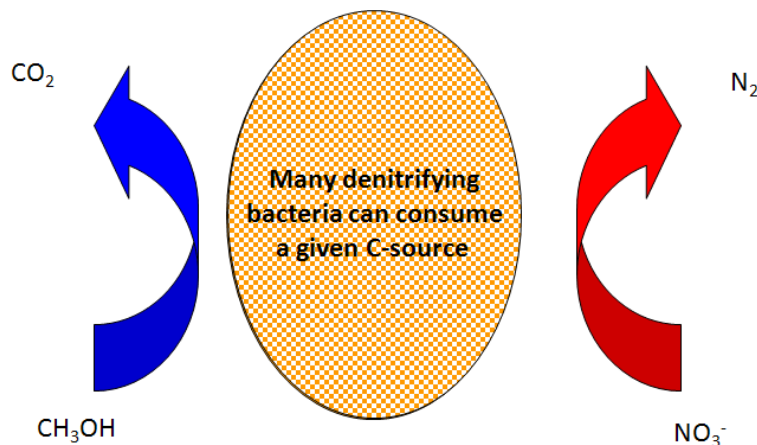

How about C-specific kinetics?

- mRNA concentrations of genes can be quantitative biomarkers of specific functional activities

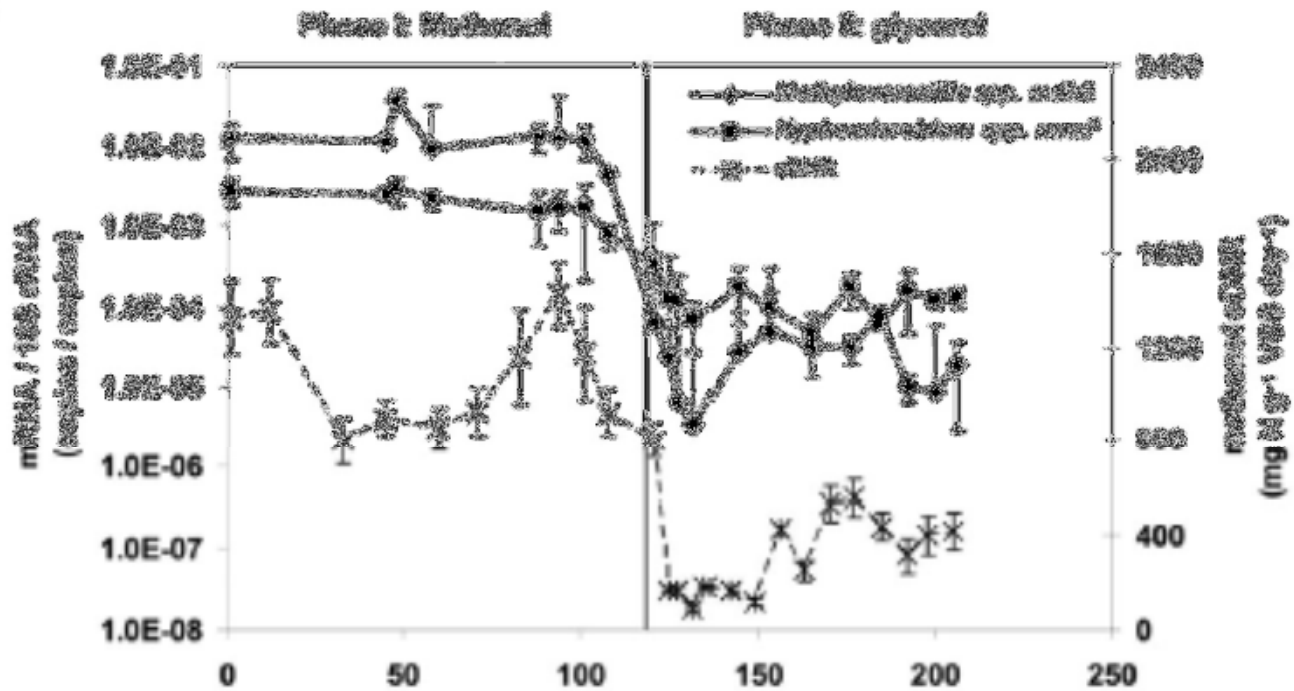

- Can discard organism boundaries and focus on functional information
→ engineering

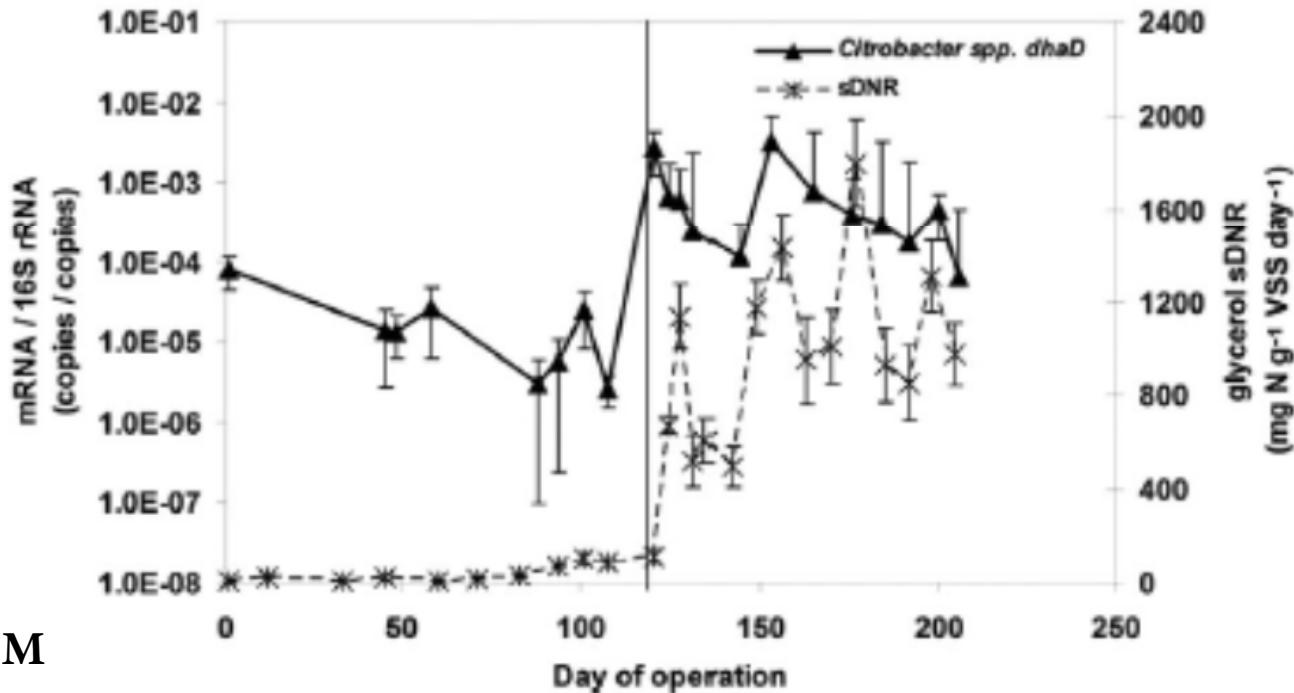

- Allows quantitative tracking of specific rates in activated sludge

(a)

(b)

Implications of activity on design

$$\Theta_{C,\min} = \frac{1}{\mu_{\max} - b}$$

- Traditional batch tests not applicable to estimate μ_{\max}
 - AOB, NOB, AMX all use NO_2^-
 - AOB and AMX use NH_3
 - Cannot infer anammox activity using NH_3 or NO_2^- depletion profiles

Estimates of activity from X_{amx} conc.

Park et al., 2010b, WR

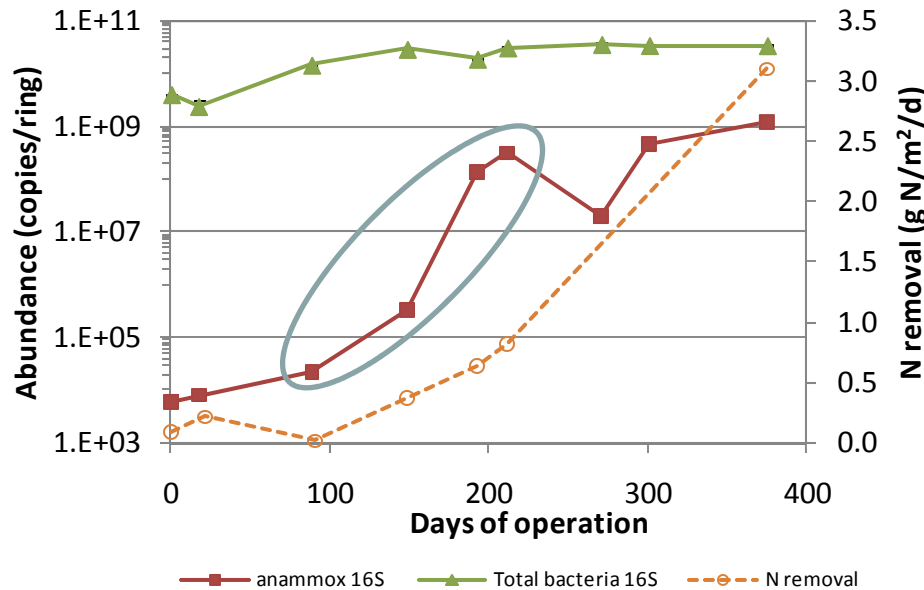

- Combination of X_{amx} with steady state mass balances to estimate μ_{max}

$$\ln X_{amx} = \ln X_{amx,0} + \mu \times t \rightarrow \mu_{max} = 0.11-0.15 \text{ d}^{-1}, t_d = 5.3 \text{ days}$$

- We don't want to rely on process upsets to estimate μ_{max}

Measures of anammox activity

$$t_d = \frac{\ln(2)(t - t_o)}{\ln \frac{C}{C_o}}$$

- $t_d = 8.9$ days
- Another utility of directly measuring X_{AMX}

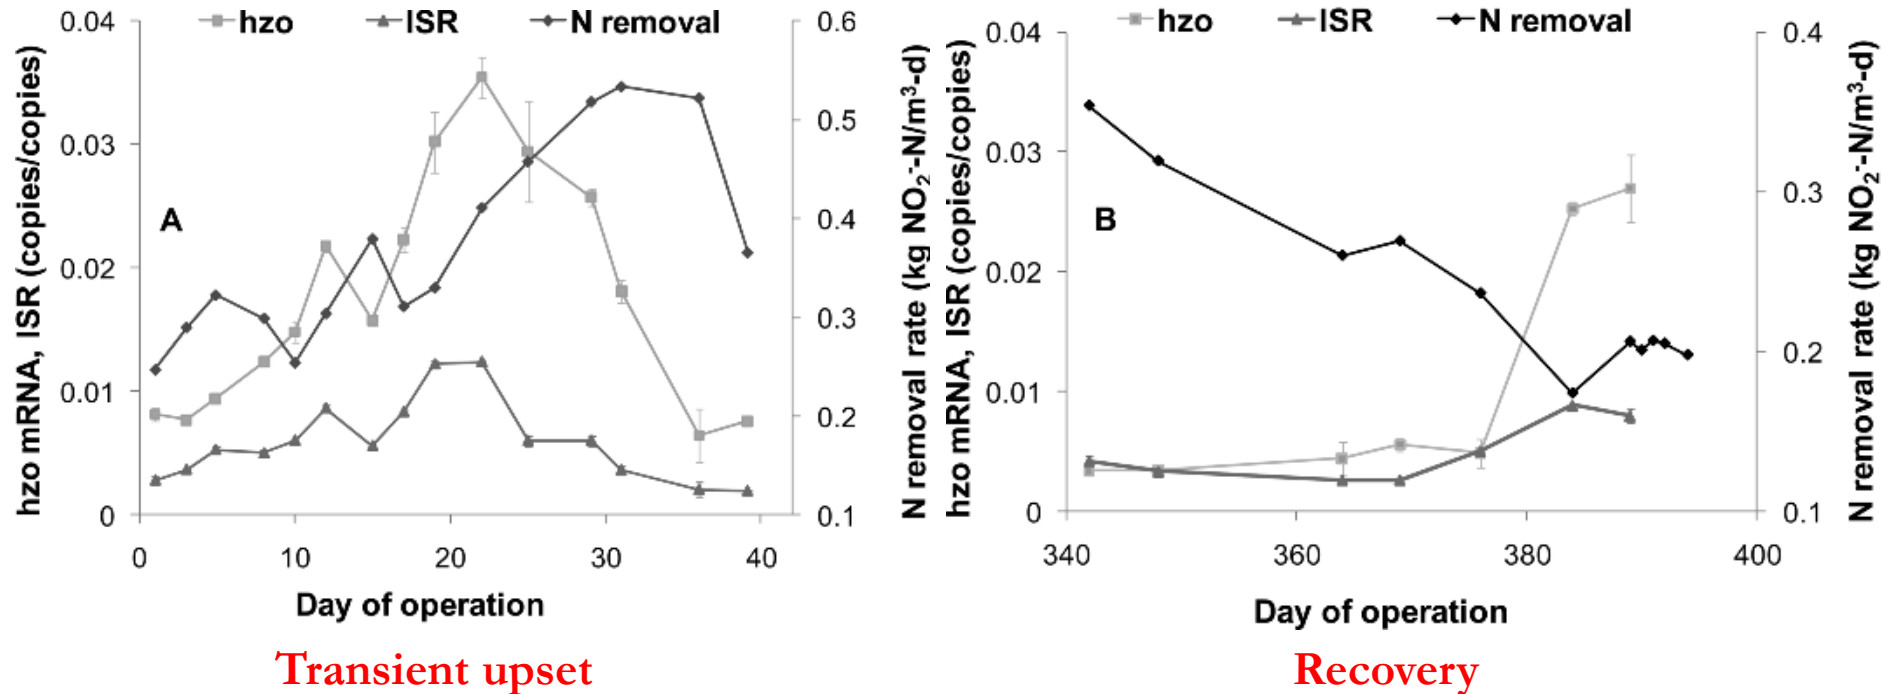

Transcript abundance as an indicator of activity?

- Intergenic spacer region (ISR) between 16S rRNA and 23S rRNA has been used before to describe anammox activity (Schmid *et al.*, 2005)
 - ISR is not a biomarker of anammox reaction specific activity
- HZO (HAO)
 - Structurally and functionally unique
 - Reaction specific to anammox pathway

hzo and ISR based tracking of *in-situ* anammox activity

- Trends in fold expression relatively consistent for both *hzo* and ISR
- Conceptually, changes in molecular responses should ‘precede’ whole-reactor changes
- Especially important in high SRT systems where performance upsets significantly lag biocatalyst activity

**CAPPED
SECTOR**

CO₂

**Less
N₂O**

**Less
Nr**

**NON-CAPPED
SECTOR**

The inventory in autotrophic AOB

MG Klotz & YL Stein. 2011.

In: Nitrification. Ward, Arp & Klotz (Eds.), pp. 57-93.

The inventory in autotrophic AOB

- Multiple routes for N_2O production in AOB
- Controlled by electron flow and conc. of electron carriers
- Release valve for electrons
- N_2O is the terminal product

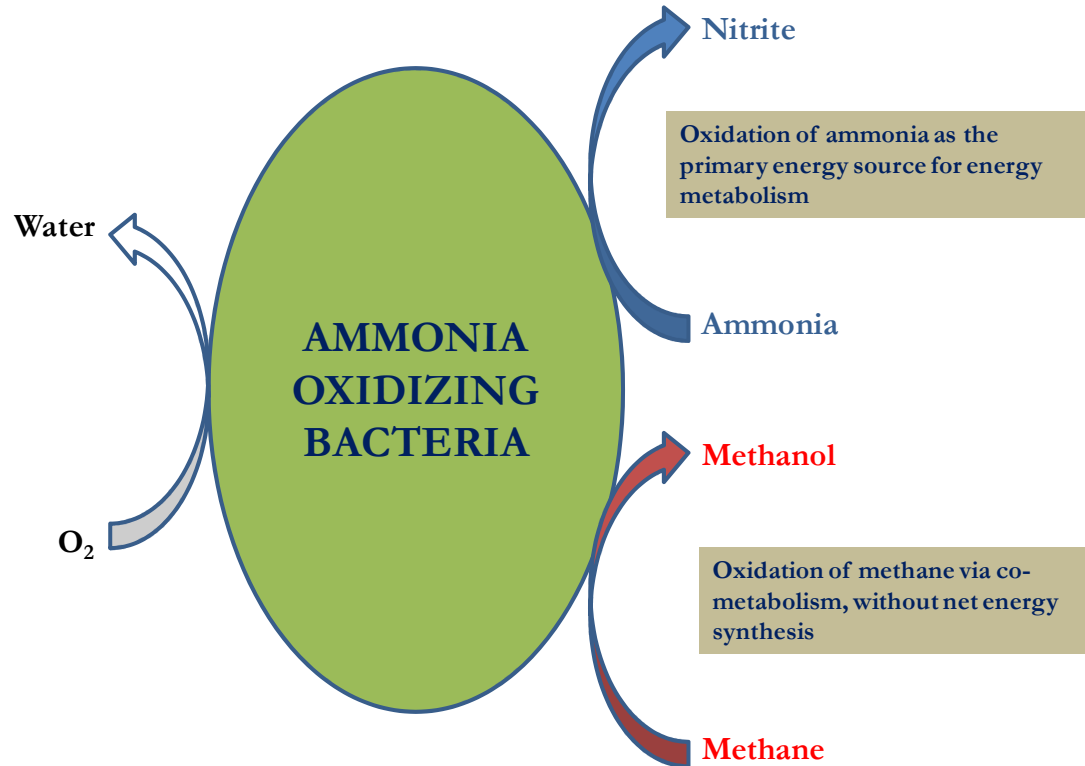

MG Klotz & YL Stein. 2011.

In: Nitrification. Ward, Arp & Klotz (Eds.), pp. 57-93.

Chemical Recovery

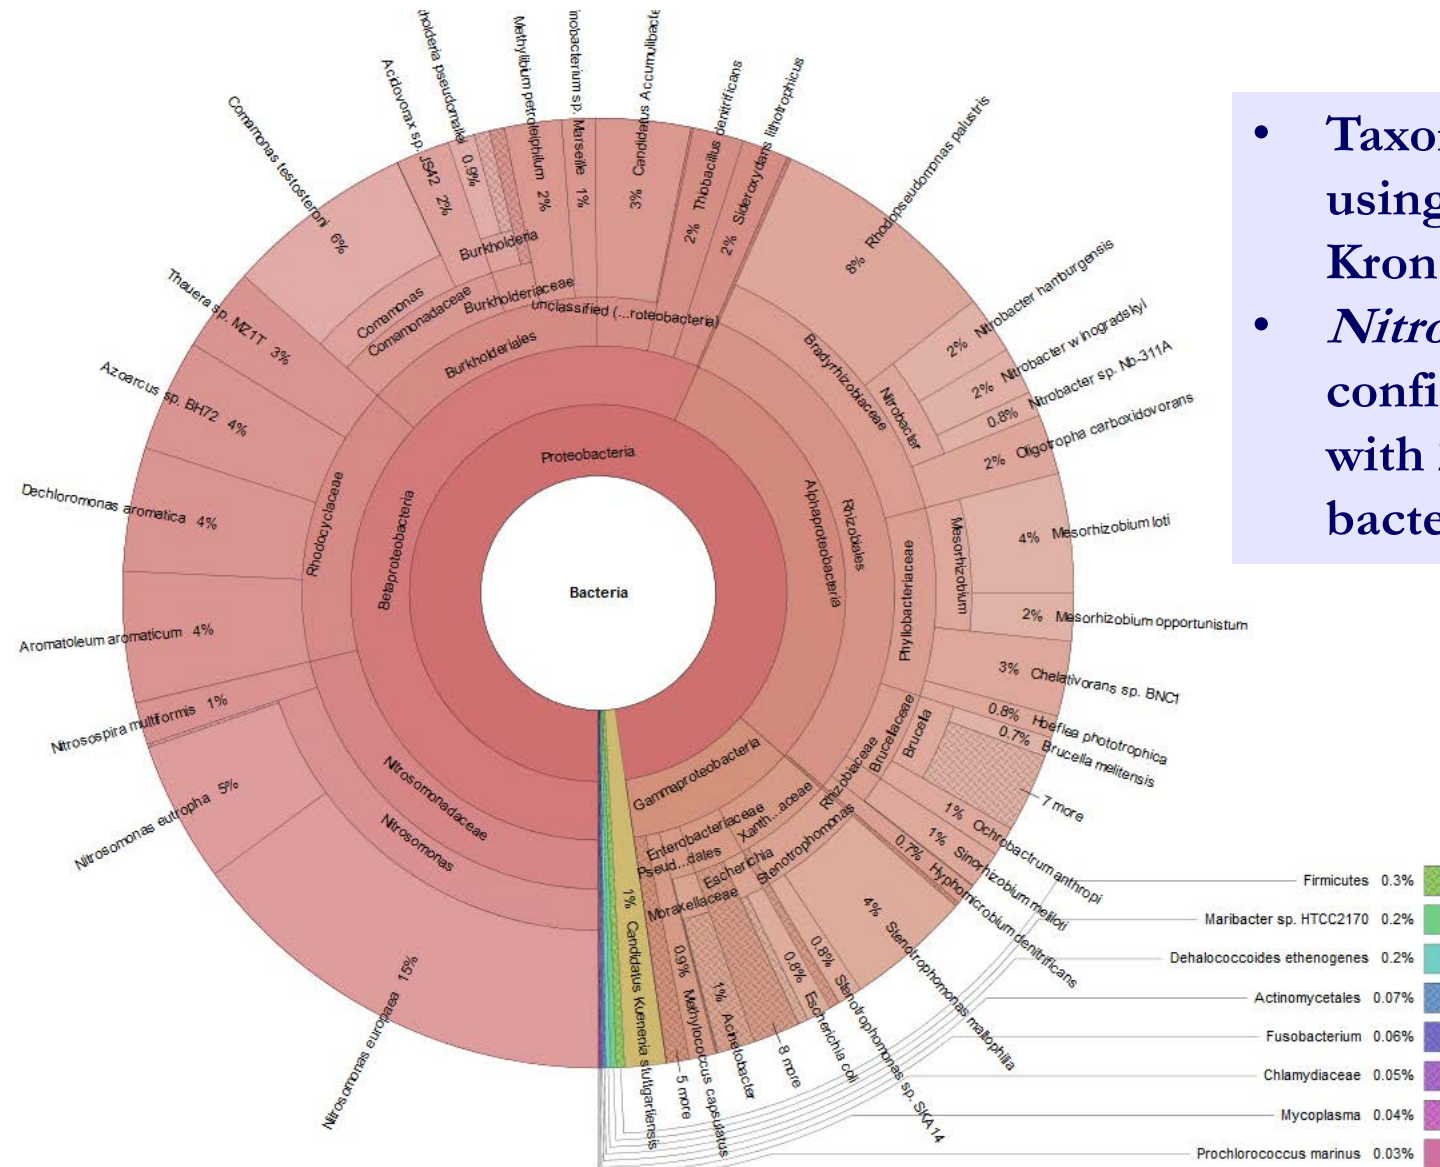

Methane to bio-methanol

- Concomitant oxidation of CH₄ and CO₂ fixation
- Prospect of combining C & N cycles

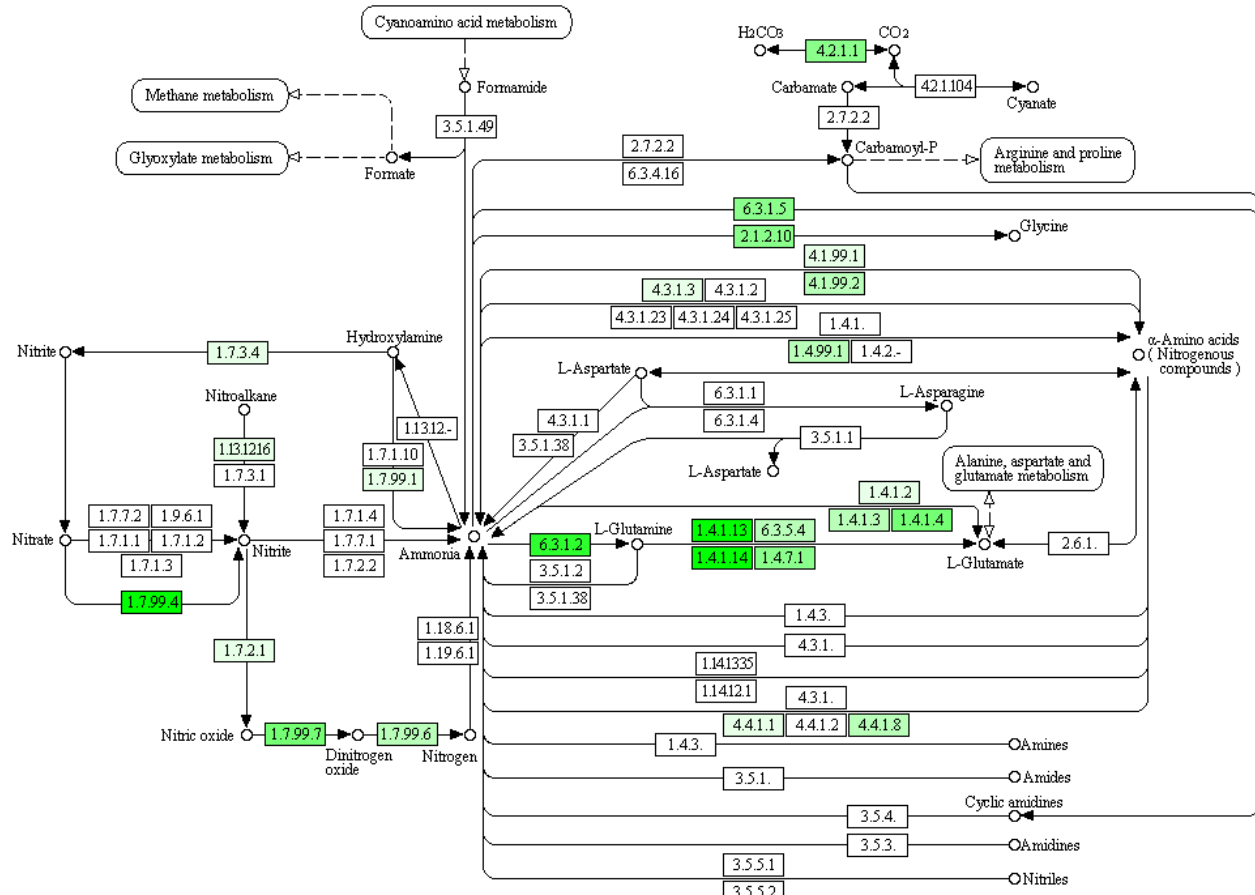

Results – CANON Metagenome (suspension)

- Taxonomical analysis using; MG-RAST with Krona graph
- *Nitrosomonas* was confirmed dominant with 21% of total bacteria.

Results – CANON Metagenome (suspension)

NITROGEN METABOLISM : REDUCTION AND FIXATION

- Glimpse of ‘potential’ pathways existing (quantitative as well)
- Color intensity describes relative concentrations

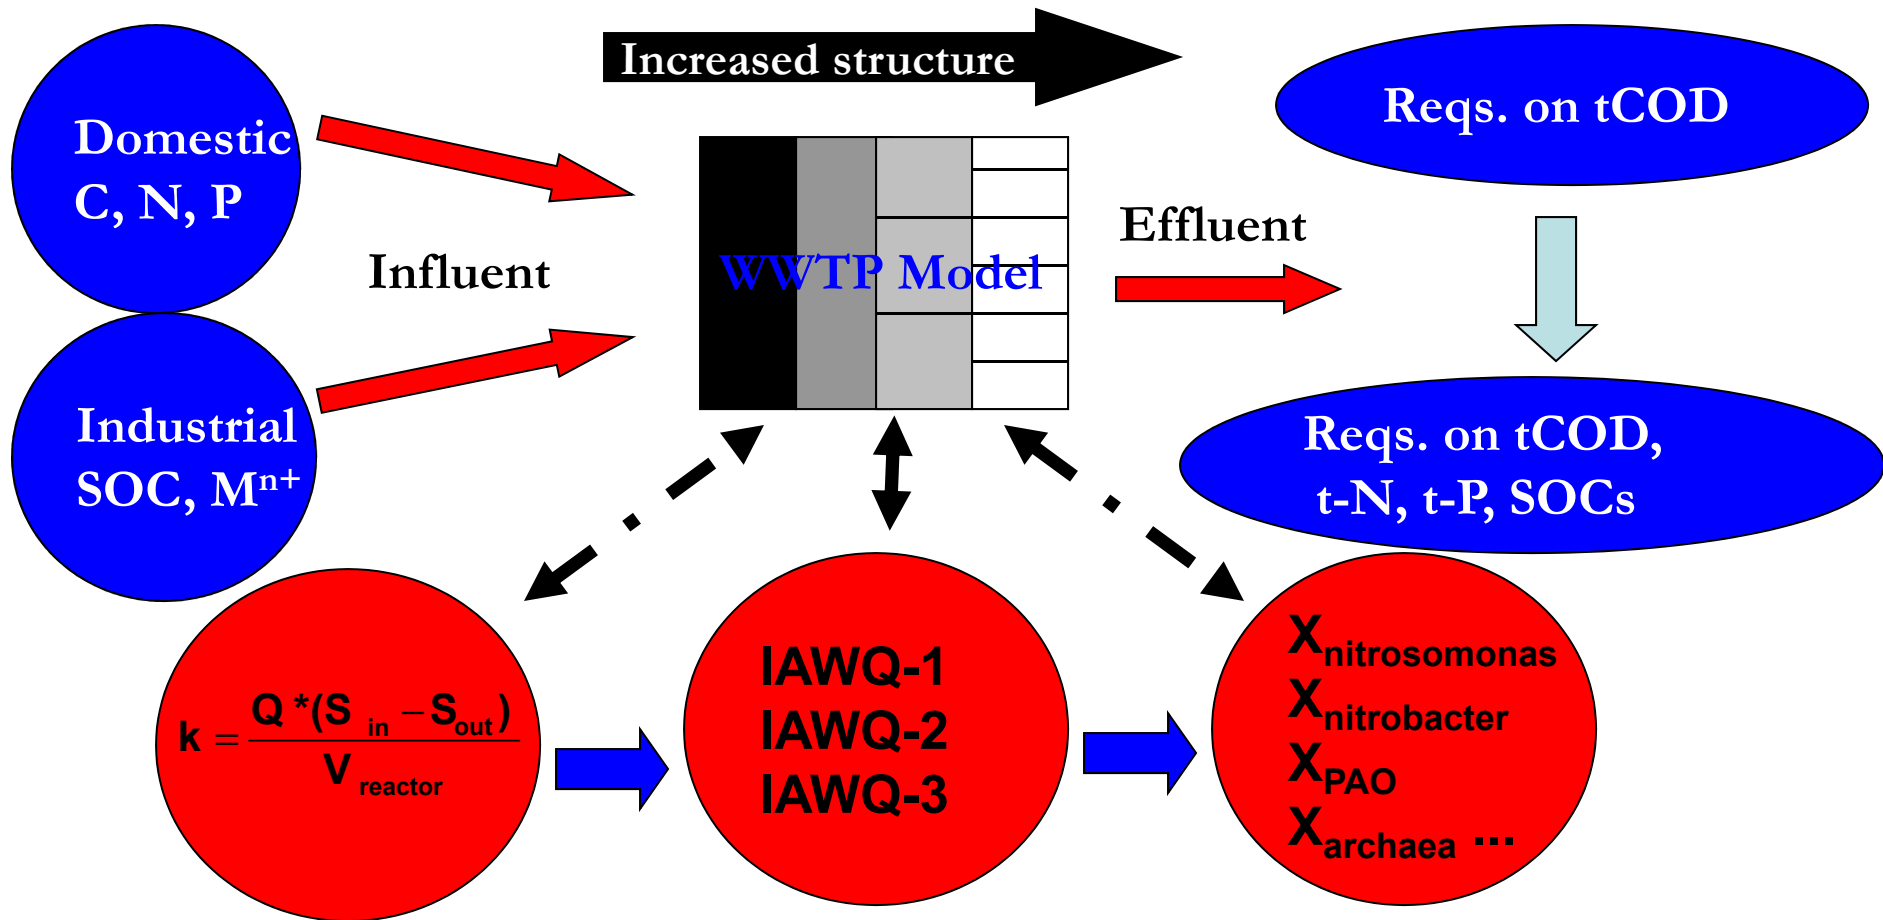

The holy grail (for today)

- Individual molecular measures of activity
 - N-oxidation
 - C-oxidation
 - Multiple substrate oxidation by same bacteria
 - Gene expression can work for select reactions

Evolution in characterization of biochemical waste treatment processes

- Composition (Structure) + Activity (Biokinetic)
